

Aberffraw to Porth Cwyfan

Enjoy fascinating geology and magnificent scenery on this beautiful walk on the west coast of Anglesey. Dr John Conway (GeoMôn – Anglesey's geopark & Royal Agricultural College)

Pictures: J. Conway, unless stated otherwise

Length: 4km each way
Time: 2-3 hours
Difficulty: easy
Start/Parking: The old Packhorse Bridge, Aberffraw SH 355 689.

Starting point: The old Packhorse Bridge, Aberffraw 1 This geotrail follows the coastal footpath all the way along the rocky shore to Porth Cwyfan. As you walk down the western bank look across the river to Tywyn Aberffraw 2, a vast area of sand blown ashore during massive storms in 1331, fronted by Traeth Mawr, a beautiful sandy beach backed by the dunes.

On the headland, Tywyn Du 3, flints and other remains have been found dating back over 8000 years to the Mesolithic period – in those days it would have overlooked a low coastal plain, its topography offering a chance to drive game against what is now the cliff line and into an ambush – this is seen even more clearly just along the coast at Porth Tre Castell. All that is visible now is a very low circular feature from the Bronze Age.

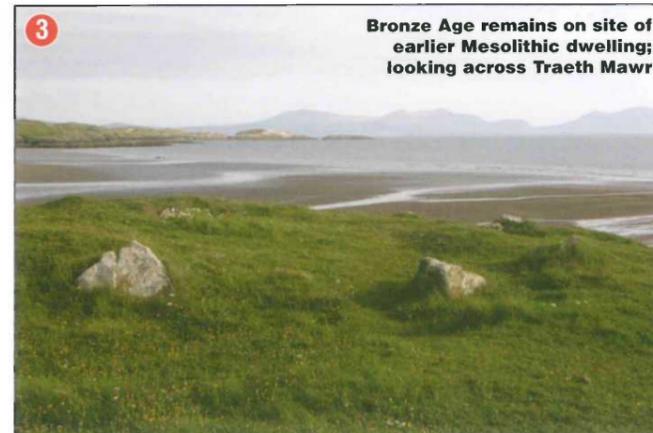

View across the Afon Ffraw towards Tywyn Aberffraw, the vast expanse of sand dunes

Across the head of the first sandy cove, Porth Lleidïog 4 vegetation is colonising a shelf at the top of the beach, this is a small 'raised beach' – a feature created by the land rising slowly out of the seas after being depressed by the ice sheets though due to global warming means it is threatened by rising sea levels. At the far side of this cove, glacial deposits can be seen sitting directly on the ice eroded rock surface 5 – if you back and you will see large boulders lying on the shore – these are 'erratics' left exposed as the sea erodes the finer material from the glacial deposits. From here into Porth Cwyfan, if you look generally at the rock platform [ignoring

the erosion cutting into it] a smooth, gently curving surface can be determined, and in places, especially close to eroding soft deposits, it may have a smooth, even polished surface. This represents the ice-eroded rock surface that has been dissected by wave action into a jagged irregular surface. Follow the coastal path, admiring this smooth glacially eroded rock surface, and the excavation of deep inlets by the sea along faults and fractures in the rock. As you pass the headland with an offshore reef (Carreg-y-trai) look carefully into the next little bay 8 - before the headland with a rusty windlass - and note the transition from the Gwna green

Bronze Age remains on site of earlier Mesolithic dwelling; looking across Traeth Mawr

schists you have been crossing to slightly more metamorphosed silvery grey mica schists.

Porth Cwyfan

Rounding the headland brings us into a large rocky cove unique in having a small church on an island in the middle of the bay. The glacial deposits that once filled the bay can still be seen as a low cliff at the head of the beach. Just beyond the track that comes down onto the beach, you can see deep, narrow V-shaped features 7 usually very pale in colour lined by an orange or rusty coloured rim; these are ice-wedge casts, features formed towards the end of the ice age when this area was permafrost. The soil here is a brown earth, a very fertile if somewhat stony soil, with gradual changes in appearance of soil properties down the profile. The topsoil is frequently

View across ice carved rocks to Porth Cwyfan

almost free of stones, the result of earthworms casting fine soil onto the surface and allowing the stones to be concentrated at the base of this layer. Further round, this glacial deposit thins as you approach the stream entering the bay 8. There is a layer of rusty, black or reddish coloured material, often very hard and forming a protruding ledge near the base of the soil, this is an iron pan caused by "gleying" – a process whereby the very wet conditions cause an absence of oxygen which in turn affects the chemistry of iron (and manganese) creating nodules or leading to cemented layers. A little further on the top of this layer looks like a conglomeration of small spherical pebbles, these are actually concretions or nodules of manganese.

The origins of the church 9 are lost in the mists of time, reputedly founded in 605 by St Cwyfan (Kevin), but the current structure was built in the 11th century at twice its present size. The

Erratics (boulders carried by the ice) left stranded on the shore

Soil formation within the glacial sediments in Porth Cwyfan

church originally stood on a promontory of boulder clay but subsequent erosion not only left it isolated on an island, but undermined the northern half of the church. What we see today is the result of 19th century remedial works, including the stone wall that surrounds the island. The bay beyond the causeway is known as Porth China, apparently a reference to mining boulder ["china"] clay, not suitable for china but it may have been used for bricks or pottery.

You can retrace your steps along the coastline, or take the track up to Llangwyfan-isaf then turn right and follow the footpath back to Aberffraw, or follow the road.

Stunning views from the Aberffraw coastline across to Pen Llyn
